Who Decides New York?

The off-year electorate, resolved by party — from 13.5 million individual registration and vote records

Stephen Kirby · Tikor Consulting · July 2026

AI-assisted drafting and analysis review. All figures are reproducible from public-record data available through lawful request and from the open-source scripts cited below, including `scripts/verify_who_decides_ny.py`. *The paper source, code, and data-acquisition recipe are public at https://github.com/skirby359/who-decides; the underlying voter file is not redistributed. Contact: kirby@tikorconsulting.com.*

Party-resolved companion to `who-decides-washington.md` *and* `who-decides-idaho.md` *(the deep-red counterpart). Washington showed the off-year electorate is older; New York publishes each voter's party enrollment, so here we can ask the question Washington could not — which party's electorate is older, who is ineligible for the nominating stage, and how one-sided the registration map is. DRAFT — pending human/editorial sign-off.* `scripts/verify_who_decides_ny.py` *scrapes this paper and asserts its figures against the voter file, with the exceptions the script names in its own output; see* `electoral-health-audit-log.md`. *That gate is automated and is not the sign-off. The sign-off is a person reading the paper end to end, recorded in* `ny-submission-notes.md` *§Sign-off.*

An earlier version of this line said the paper had been verified because "all `verify_*` *scripts re-run, exit 0". That was worth nothing: until 2026-08-01 this paper's verifier had no assertions and no failing exit path, so it printed values for a human to compare and returned 0 whatever the data said. When it was converted to assert, §II and §III did not reproduce and have been recomputed — see the note under §III.*

Provenance. The voter-file figures come from `data/ny_vrdb.duckdb` *— New York's NYSVOTER statewide file (13.54M registrants; individual party enrollment and full DOB 100% populated, plus per-event vote history for the 82.9% of registrants carrying any recorded event — this file's vote history begins in 2016, so a registrant with no recorded event may simply not have voted within that window; the share is a turnout-and-window fact, not a missing field) — via* `scripts/diag_ny_turnout_party.py`, `scripts/diag_ny_primary_participation.py`, *and* `scripts/diag_ny_electorate_extras.py`. *Two figures come from elsewhere: district competitiveness from* `forecast_predictions`, *and §II's matched-donor rates from the donor paper's matched contribution panel. Appendix C additionally compares the file against the New York State Board of Elections' published enrollment series, via* `scripts/diag_ny_enrollment_validation.py` *— the one place external aggregate enrollment data enter the voter-file analysis. Each figure below traces to one of these sources.*

Load-bearing caveats, both temporal, both revised 2026-08-11 after external review.

(1) Party of record is CURRENT enrollment, not enrollment at the election analysed. **NYSVOTER carries one enrollment field and no history of it, so every party-resolved historical cut here reads "voted in year Y, enrolled X in 2026." New Yorkers may change enrollment, so those are not the same population. The drift is bounded, not assumed: a closed primary is open only to enrollees, so everyone in §III's numerators was enrolled at the time, and** 0.7–1.4% of them are enrolled blank today **— under half a point a year of movement out of the major parties among primary participants. Movement** between **the two major parties leaves no trace in a single extract and is** not **bounded here. §II's cross-sectional results, which describe the 2026 roll, are unaffected.** Appendix C* *compares the reconstructed aggregate party shares for past dates against NYSBOE's published series; that validates aggregate composition, not any individual's party at the election analysed.*

***(2) The file is the current roll*, so voters who cast a past ballot and were since purged are absent. Participation** rates **are denominated on registrants enrolled in time to vote (§I, §III). Composition** shares **are less denominator-sensitive but are not immune, and an earlier version of this line called them "robust" and claimed the bias "hits every group equally" — neither was established. Measured instead, using inactive status as the visible pre-purge state: attrition is near-flat across parties (0.35pp spread) and** not **flat across age — the under-30 band leaves at twice the 45–64 rate, so the age shares understate youth in past electorates. See "Boundary of inference" and** Appendix C**, which compares the reconstructed aggregate party shares against NYSBOE's published series and finds them differing by at most** 1.39 points* *across the 2021–2026 snapshots it tests — a measured discrepancy over those snapshots, not a bound over the older elections §I also uses, and not a bound on any voter's party at a past election or the age-within-party finding.*

"NOPARTY" = New York's blank/no-party enrollment; its lean is never imputed.

Abstract

How many people vote is the wrong question for understanding how a state is governed; the right one is who. New York has

filled most local offices in odd-year Novembers and conducts its party nominations through closed primaries, and its voter file records each registrant's party of record — so the question can be answered with the variable that matters most. Using the full statewide registration file and per-election vote history for **13,540,505** registrants, this paper measures the composition of each general electorate and of each nominating electorate. The off-year electorate is markedly older: the 65-and-over share rises from **28.2%** of the 2024 presidential electorate to **41.6%** in the 2023 odd-year general while the under-30 share collapses from **14.1%** to **6.0%**; separately, a decomposition of the 2024-to-2025 increase attributes that change several times more to differential turnout than to registration-age composition. Party of record shows the off-year age skew is **party-structured** — classifying each historical electorate by voters' current (2026) enrollment, the only party variable the file carries (front-matter caveat 1): Republican off-year electorates are consistently older than Democratic ones and the no-party bloc is younger than both, and in the 2025 odd-year electorate the Republican median voter is **62** against the Democratic **54**, an eight-year gap that is roughly five years at the presidential level. A quarter of registrants, **25.3%** of the active roll, enroll in no party; they are the youngest of the state's major enrollment blocs, the least participating, and the least likely to appear in matched political-contribution records, and while unaffiliated they are barred by law from the nominating stage. Participation in those primaries runs from under two percent to the high teens, and by registration only **21** of **176** congressional and Assembly districts are within five points. Registration records dated in recent years are markedly less likely to carry a party — a description of the current roll by most-recent registration-event date, which does not identify successive cohorts of first-time entrants. New York has since legislated part of the remedy these patterns point to — Chapter 741 of 2023 moved many town and county elections to even years, first operative in 2026 — which makes the electorates measured here a statewide pre-transition benchmark; a causal follow-up should restrict the comparison to the jurisdictions and classes of office the statute actually moves. The paper reports composition, not preference, and imputes no partisan sympathy to unaffiliated registrants.

Keywords. off-cycle elections; election timing; voter file; party registration; closed primaries; turnout composition; unaffiliated voters; nominating electorate; state legislatures; New York

The question

How *many* people vote is the wrong question for understanding how a state is governed. The right one is *who* — and in New York the answer changes dramatically with the calendar, because local offices have been filled in odd-year Novembers and party nominations are made in low-turnout closed primaries that a quarter of registrants cannot enter. New York lets us answer "who" with the variable that matters most: **individual party of record.**

The short answer: **the off-year electorate that decides New York is older than the high-salience one, the age skew is party-structured, and a quarter of registrants cannot take part in the nominating stage while they remain unaffiliated.** That the off-year electorate is older replicates a sixty-year-old literature and is established here in **Appendix A**, where it belongs. What New York's party of record adds — and what we have not found shown at this scale on individual records — is that off-year electorates are consistently oldest on the Republican side and youngest in the no-party bloc, and that the bloc excluded from the nominating stage is the youngest and least engaged of the state's major enrollment blocs.

I. The graying is party-structured — Republican off-year electorates are the oldest

This is the cut Washington's data cannot make, and it is this paper's contribution. Appendix A establishes the premise the off-cycle literature already predicts: as salience falls, the electorate ages. The question that premise leaves open is *which party's* electorate is older, and whether that ordering persists across election types — and it does. Share of each party's voters who are 65+:

Election	DEM	REP	NOPARTY	OTHER	R − D
Nov 2016 (pres)	19.8%	22.5%	16.1%	16.4%	+2.7
Nov 2017 (odd)	28.8%	30.0%	25.5%	23.4%	+1.2
Nov 2019 (odd)	32.1%	35.8%	31.2%	28.4%	+3.7
Nov 2020 (pres)	22.7%	26.8%	18.3%	20.3%	+4.1
Nov 2021 (odd)	36.6%	37.5%	34.1%	31.6%	+1.0
Nov 2023 (odd)	41.6%	43.5%	39.3%	37.4%	+2.0

Election	DEM	REP	NOPARTY	OTHER	R − D
Nov 2024 (pres)	28.7%	32.4%	22.2%	27.0%	+3.7
Nov 2025 (odd)	32.1%	**42.8%**	30.6%	35.1%	**+10.7**

Shares are of each party's actual voters. The Das-Gupta decomposition in `ny-electorate-extras.md` §3 uses all-roll-matched bases for the 2024 presidential row (DEM 29.0 / REP 32.7 / NOPARTY 22.4), ~0.3pp higher.

The claim this section makes is about levels, and it holds in every general the file contains. Across all **8** general elections in the vote history — **5** of them odd-year — the Republican electorate is older than the Democratic one on the 65-and-over share, **8 times out of 8**, and the no-party bloc is younger than both, also **8 out of 8**. The ordering never once reverses.

This table showed three rows until 2026-08-17, and a self-flagged review item called the resulting n=2 a weakness — while also asserting, wrongly, that the file held only two odd-year generals. It holds five. Measuring all of them turned the caveat into a result: what looked like a two-observation claim is an eight-for-eight one, and the extension was the right response rather than the hedge. The correction is recorded because the error was in the fix, not in the original finding.

The gap does NOT widen off-cycle, and that is the fifth independent reason "ages hardest" is withdrawn. Excluding 2025, the R−D gap in odd years runs **+1.0 to +3.7**; in presidential years it runs **+2.7 to +4.1**. The two ranges overlap and the presidential one sits, if anything, slightly higher. The observed odd-year electorates do not show a wider partisan age gap; both party electorates are older together. **2025 (+10.7) is more than double the widest gap in any other general in the file**, and it is an event-specific outlier, not a calendar effect. Median age says the same: in the 2025 off-year the **Republican median voter is 62 against the Democratic 54**, a gap of eight years where the presidential electorate's was about five.

A stronger, dynamic version of this — "the Republican electorate ages hardest" — was this section's heading and stated contribution until 2026-08-16, and the table does not support it. Measured against 2024, the Republican 65+ share rises **+10.4** points into 2025 against the Democratic **+3.4**, which is the case that framing was built on. But into **2023** the Democratic share rises **+12.9** against the Republican **+11.1** — the ordering reverses. With two odd years pointing opposite ways, "ages hardest" is a claim about which contest was on the ballot, not about salience. The cross-state companion `who-decides-cross-state.md` reached this conclusion first and said so plainly; this paper did not carry the correction across, which is the propagation failure the series is meant to catch. What replaces it — Republican off-year electorates are consistently the oldest, and the no-party bloc consistently the youngest — survives every row and is the durable result.

The right reading of 2025 is event-specific, not a calendar effect. New York's Republican odd-year 65+ share climbed over the five odd years to a peak of 43.5% in 2023, then 42.8% in 2025 — not a monotonic rise; across those last two it is the *Democratic* share that swings, from 41.6% in 2023 to 32.1% in 2025. The statewide data here do not identify what drove the 2025 Democratic electorate younger — the 2025 general was not a single contest, and separating the New York City ballot from the rest of the state would be needed to attribute it — so 2025 is best read as an event-specific outlier, not as low salience ageing one party more than the other.

That the Republican electorate is the older one is itself a New York fact, not a law of nature: the deep-red companion, `who-decides-idaho.md`, finds senior-share parity — Idaho's Democratic and Republican electorates are within a fraction of a point (65+ share 31.5% vs 31.7% in 2024) — while at the young end its Democratic and unaffiliated electorates are essentially level (18–29 share 19.4% vs 19.6%) and its Republican electorate sits well below both (12.7%). Whose electorate is older is contingent on the state; *that* the low-salience electorate is older recurs in both.

This paragraph said until 2026-08-17 that in Idaho "the youth that drops off in low-salience contests sits in the unaffiliated and minor-party blocs, not in one major party." That is false against the companion's own table — Idaho's Democratic and unaffiliated electorates are level at the under-30 end — and the companion withdrew the same sentence on 2026-08-15. It is the shape of defect this series keeps producing: a corrected result in one paper reaching every other paper that cites it. The senior-share parity, which is what this paragraph needs, is unaffected.

But the *composition* heuristic that "older off-year electorate ⇒ more Republican" **does not hold in deep-blue New York.** The DEM–REP share gap among actual voters does not track aggregate turnout in the simple way that heuristic assumes — it swings from +15.6 (2023) to +33.2 (2025) depending on what's on the ballot, so lower turnout does not mechanically produce a more Republican electorate here (differential turnout by party and age still shapes who votes, as the rest of this section describes) — and the unaffiliated, not either party, are the ones who drop out (25.5% of the roll, but only 16–22% of voters — over the **three most recent** generals, 2023–2025). *That scope is deliberate and was made explicit on 2026-08-17, when §I's table was extended back to 2016. Over all eight generals the voter range runs from 14.5%, but the blank bloc has grown across that decade, so pairing a 2026 roll against a 2016 electorate would overstate the drop-out this sentence is about. The*

wider figure is the growth of the bloc, not evidence of exclusion. And in even-year federal contests Republicans out-turn Democrats at *every* age, yet in the 2025 general's under-30 cell that ordering reverses: Democratic under-30 turnout (32.8%) was nearly **double** Republican (16.6%) — the share of each party's under-30 active registrants **enrolled on or before election day** who returned a ballot. Party-resolved, the signal lives in age structure and youth mobilization, not in a simple rightward headcount shift.

Two phrasings were withdrawn from this section in the 2026-08-30 referee round. An earlier draft read the 2025 gap as a single mayoral contest that mobilised Democrats young — a causal attribution the statewide data here cannot support, 2025 being an event-specific outlier — and called the DEM–REP composition gap event-driven, not turnout-driven, which overstates the case, since differential turnout by party and age does shape who votes; the surviving claim is only that lower aggregate turnout does not mechanically produce a more Republican electorate here.

II. The unaffiliated quarter: young, disengaged, and outside the primary

A quarter of New York registrants (25.3% of the active roll; 25.5% of the full roll) enroll in no party. This section is **cross-sectional** — it describes the 2026 roll, so the temporal caveat on party of record does not reach it — with one exception: the 2024-turnout column is an event rate, and like every rate in this paper it is denominated on registrants enrolled on or before that election (see the correction note under §III's table).

	median age	%65+	%18–29	2024 turnout	matched donors / 1k
DEM	49	26.5%	18.0%	60.5%	55.3
REP	55	30.4%	14.9%	**70.8%**	48.5
NOPARTY	**42**	17.4%	**25.6%**	**53.1%**	**22.7**

"Matched donors / 1k" is the rate at which each party's active registrants appear in the donor paper's matched contribution panel (FEC plus New York State disclosure, full-name key) — not a measure of giving in general, and not a dollar figure. The ordering is not an artifact of that match specification: on the retired 308,032-voter panel the NOPARTY-to-DEM ratio is 0.375 against 0.412 here. The composition columns describe the whole pinned active roll; the turnout column's denominator is the subset enrolled in time to vote in the 2024 general.

Of the three enrollment categories shown, the blank bloc is the **youngest, least likely to vote, and least likely to appear as a political donor**. What it is *not* is measured here: we observe no information level, no ideology, and no partisan sympathy. And under New York's **closed** primaries, registrants who are unaffiliated at the applicable primary-eligibility deadline cannot vote in a party primary; the roughly one-quarter unaffiliated on today's active roll are a current snapshot of that bloc, not a fixed membership, and have no voice at the party-primary nominating stage. Enrollment can be changed, and the statutory deadline for doing so falls in February of the primary year; the finding is that a quarter of registrants do not.

III. The nominating electorate is smaller still

New York makes its party nominations in primaries that only enrollees may vote in, and most of its legislative districts carry a registration imbalance large enough that the party-primary nominating stage is an obvious place to look for consequential contests (§IV). **This paper does not determine the stage at which any individual seat became effectively decided** — that requires tracing each seat through its primary and its general, which is future work and is stated as such in §IV. Earlier drafts of this sentence and of the abstract said New York "settles most legislative seats" in primaries; that is a stronger claim than a registration map can carry, and the companion safe-seat paper withdrew the equivalent inference on *observed margins*, which are better evidence. Participation rate by enrollment — voters as a share of that party's active registrants **enrolled on or before that primary**:

Primary	DEM	REP	NOPARTY	OTHER
2024 Presidential	4.8%	4.9%	0.1%	0.2%
2024 State/Congress	7.7%	1.7%	0.1%	0.6%
2022 State/Congress	17.9%	18.4%	0.6%	2.0%

Primary	DEM	REP	NOPARTY	OTHER
2021 (odd-year)	16.9%	5.0%	0.5%	1.5%

Two facts: primary turnout runs from single digits to the high teens — the electorate that *nominates* is a small fraction of the one that *elects* — and the **25.3% enrolled "blank" today are near-absent from these primaries by current classification** (≈0.1–0.6%). In blue New York the **Democratic primary draws far more participation than the Republican** in the contests that matter most locally (2021 odd-year DEM 16.9% vs REP 5.0%; 2024 state DEM 7.7% vs REP 1.7%).

What the NOPARTY cells actually are. An earlier version read the 0.1–0.6% residual as "nonpartisan/special races." That reading does not survive its own test. A closed primary is open only to enrollees, so a voter recorded in one who is enrolled blank *today* changed enrollment in between — and the **2024 presidential** primary settles which mechanism dominates, because no nonpartisan contest appears on that ballot anywhere in the state and its blank cell is still non-zero. Read the other way, these cells are the paper's switching bound: of the voters in each closed primary, **0.7% (2024) to 1.4% (2021) are enrolled blank today**. That is the only enrollment drift a single extract can see; movement between the two major parties is invisible here.

> **The denominator of this table has been wrong twice, in opposite directions, and the record of both is kept here — with a third instance, in §II, found by the round after the one that wrote this note.** Every rate in §III, the under-30 pair in §I, and §II's 2024-turnout column is **roll-denominated**: a participation rate whose denominator is a slice of the registration file. Appendix A and the rest of §I are **electorate**-denominated — the set of people who voted in a past election cannot change when registrants are added — which is why they have been stable throughout and why the split between the two identifies the denominator as the cause whenever these figures move.
>
> **2026-08-01.** §II and §III did not reproduce when this paper's verifier was converted from printing values to asserting them, and both were recomputed against the roll as it then stood, with the divergence attributed to growth in the file.
>
> **2026-08-11, after external review: that recomputation introduced an error and misdiagnosed its own cause.** A participation rate must be denominated on the people who *could* have voted — active registrants enrolled on or before the contest. The recomputed figures were denominated on the whole current active roll, which counts someone who registered in 2025 as a 2021-primary non-voter. **20.55%** of today's active roll registered after the 2021 primary, and restoring the cutoff moves the rates **+0.13 to +2.67 points** across the eight major-party cells, largest on the oldest cycles. The table above is on the corrected basis.
>
> Three things make this checkable rather than a matter of judgment. The contemporaneous basis reproduces the figures this paper carried *before* 2026-08-01 — 16.9 and 17.9 — exactly. Roll growth explains none of the gap: the pinned and live rolls return the uncorrected 14.26% alike, to the last digit. And `scripts/diag_ny_primary_participation.py`, which the Methods block names as this section's provenance, has applied the cutoff since its first commit — so for one week the paper and its own cited script disagreed by up to 2.67 points, and both were public. The lesson is the one this series already writes down in the other direction: when a verifier and a paper disagree, the verifier is not automatically right.
>
> **No finding changes under either correction.** The blank bloc is still the youngest and least participating group by a wide margin; Democratic primary participation still far exceeds Republican in the odd-year and state contests; the ordering within every column is unchanged; and §I's under-30 ratio moves from 1.96× to 1.97×.
>
> **2026-08-13, the same defect in the one cell the paragraph above missed.** The 2026-08-11 correction scoped itself to §III and §I's under-30 pair, and §II's 2024-turnout column — the only other roll-denominated rate in the paper — kept the whole-roll denominator, counting the **6.35%** of the active roll registered after the 2024 general as non-voters. Restoring the cutoff moves DEM 57.8% → **60.5%**, REP 68.7% → **70.8%**, NOPARTY 49.3% → **53.1%**; the ordering is unchanged and the blank bloc remains lowest. One caveat applies to every corrected rate in this paper alike: the file's registration date is the date of the most recent registration *transaction*, so the cutoff also removes **122,088** registrants — **1.69%** of the recorded 2024 voters on this basis — whose 2024 ballot preceded a later re-registration. They leave the numerator and denominator together, so each printed rate slightly understates the true rate over everyone enrolled in time; a single extract cannot reconstruct the eligibility history that would recover them.
>
> The donors-per-thousand column moved for a second and unrelated reason: it was still built on the pre-2026-07-27 New York match (308,032 voters) rather than the full-name-key specification now used throughout the series (558,017). It is rebuilt on the current panel here. That change raises all three figures and leaves their ordering and the ratio between them substantially intact.
>
> **The roll is pinned, so drift cannot recur silently.** New York had no snapshot on the reasoning that a static FOIL extract cannot move; it moved, and a reload is invisible to a paper that names no snapshot. `scripts/pin_ny_roll.py` freezes

> it the way Washington's is: **`ny_paper_roll`, 13,540,505 registrants, of whom 12,448,034 are active.** Every roll-denominated figure in §II and §III is computed against that snapshot, and `scripts/verify_who_decides_ny.py` fails rather than falling back if it is absent. Appendix A and Section I continue to read the file directly, correctly: an electorate is a set of people who already voted, and it does not move. Re-pinning requires an explicit `--force`.
>
> Pinning changed no figure — all asserted values reproduced against the snapshot on the day it was taken, which is the check that distinguishes freezing a number from altering one. The snapshot was re-taken on **2026-08-11** to add each registrant's registration date, which is what the corrected denominators require and what its absence had made impossible. That re-pin is likewise value-identical: every party, active-status and birth-year aggregate is unchanged, because the field was appended to the tie-break key rather than inserted into it.
>
> **The identity of the underlying extract, so that a reproduction starts from the same bytes.** The pin freezes a derived table; the source it derives from is `ALLNYVOTERS20260629.zip`, 928,142,538 bytes, SHA-256 `ea0b97ccb027b6bfce571d17f7ef19b8135e1c10ed8cbbec136f4b73e3ef4807`, obtained by FOIL request to the New York State Board of Elections and dated 29 June 2026. Publishing the digest identifies the source without redistributing it, and covers the sections that read the file directly rather than through the pin.
>
> One data-quality note the pin surfaced, disclosed because it is checkable: the NYSVOTER extract carries **53 registration identifiers twice**, 36 of them with *both* rows active, and these are not duplicate copies. **Scoped to those 36 both-active pairs**, 8 disagree on party, 25 on congressional district and 1 on birth year; across all 53 pairs the same three counts are 13, 41 and 2. *(The scope was not stated until 2026-08-10, and the sentence read as though the 8/25/1 described all 53.)* The snapshot keeps one record per identifier, chosen deterministically, so it holds 13,540,505 registrants against the file's 13,540,558 rows. The difference is four orders of magnitude below anything this paper prints and moves no figure in it; it is reported rather than absorbed because a roll ought to be one row per registrant and the raw file is not.

IV. The registration map: one-sided almost everywhere

Most New York districts carry a large registration advantage for one party. District counts by registration lean (DEM% − REP%, active roll), on **symmetric** bands:

Level	D 40+	D 20–40	D 5–20	Within ±5	R 5–20	R 20–40	R 40+
Congressional (26)	9	3	7	**4**	3	0	0
Assembly (150)	55	31	19	**17**	21	7	0

Only **21 of 176** congressional and Assembly districts — 4 of 26 and 17 of 150 — are within five points on registration; 19/26 and 105/150 lean Democratic. The asymmetry runs one way: **no New York district at either level is R+40**, so on the same threshold, 64 districts are D+40 or more by registration while none is R+40. Registration is not a result, so that is a description of the map, not a finding that any seat is safe.

The bands were asymmetric until 2026-08-11 — 40+/20–40/5–20 on the Democratic side against 5–20/20+ on the Republican, so a D+25 district was labelled "Likely D" and an R+25 "Safe R." The symmetric table above is the same data. The ±5 count, which is the finding, was never affected; the seven Assembly seats formerly shown as "Safe R" are R+20–40.

What this does and does not establish. It is a registration structure, not an election result. It says most New York districts are one-sided enough that the party-primary nominating stage is an obvious place to look for consequential contests — which is the classic Key (1949) expectation and what motivates §III. It does **not** establish that the November general is a foregone conclusion or that the primary decides the seat: registration is not a vote, a dominant party's primary may itself be uncontested, and incumbency, candidate quality and differential turnout all move general-election outcomes away from registration. The companion safe-seat paper withdrew a stronger version of that inference on **observed margins**, which are better evidence than registration; it is not reinstated here on weaker evidence. Tracing each seat through both its primary and its general to classify where a real choice existed is the test that would settle it, and it is future work.

V. Recently dated registration records are more often no-party

Party mix of the registrants on today's roll whose **registration record is dated** in each year. **Read this as a description of the current roll, not as a series of cohorts**: the sentence that heading and table can carry is "records dated more recently are less often party-affiliated", and nothing about first-time entrants:

record dated	%DEM	%REP	%NOPARTY	median age at that date
2008	57.8%	16.2%	20.7%	29
2016	51.5%	18.5%	25.6%	30
2020	40.9%	21.3%	33.7%	30
2024	**39.7%**	22.1%	**35.6%**	29

Between the 2008 and 2024 rows the Democratic share is **18.1** points lower and the no-party share **14.9** points higher, while the Republican share is **5.9** higher — the smallest of the three movements, but a rise of a third on its own 2008 level and monotonic across all four rows. *(An earlier version of this sentence called the Republican share "roughly flat", which its own table contradicts; the three movements are now stated and asserted rather than characterised.)*

`registration_date` records the most recent registration TRANSACTION, not necessarily an initial one, so these rows are not cohorts of new entrants. A move, a name change or a party change writes a new date, which means a row dated 2024 mixes genuine first-time registrants with long-registered New Yorkers who moved house. That is partly measurable — someone who voted *before* their own registration date was demonstrably registered earlier — and on that test at least **9.96%** of the 2020 row and **13.91%** of the 2024 row are re-registrations. Those are lower bounds; a re-registrant who never voted before leaves no trace. **The two percentages are not comparable to each other**: 2024 has an eight-year detection window against 2020's four, so the gap between them measures observability, not a rise in re-registration. The 2008 and 2016 rows cannot be split at all, because this file's vote history begins in 2016.

This section was headed "A leading indicator: recent registration cohorts are choosing no party" until 2026-08-16, and described the blank bloc as "growing through new registration" by "successive intakes". All of that is withdrawn. The deep-red companion, `who-decides-idaho.md`, had already made this correction on its own registration-date section and this paper did not carry it across. An earlier version also argued that because detected re-registrants are more Democratic and less unaffiliated than the rows containing them (in 2024, **48.9%** Democratic and **25.1%** no-party against **38.2%** and **37.3%** for the rest, at a median registration age of 38 against 28), the true first-time trend must be *steeper* than the table shows. **That argument is also withdrawn**: the detectably re-registered subset is not necessarily representative of all re-registrants, and the detection window differs across rows, so it cannot bound what it was being used to bound.

What survives is the cross-sectional statement, which is worth having on its own: recently dated records carry no party far more often than older ones, and — per §II–III — remaining unaffiliated is also a choice to sit out the nominating stage. It does **not** establish a demographic trend in new entrants, and it is not a forecast of future electorates. (Survivorship caveat, unchanged: only registrants still on today's roll appear at all.)

Boundary of inference

- **Party of record is 2026 party.** The single largest limitation, and the one a reader should carry into every historical table with a party column. See caveat (1) in the front matter for the bound: 0.7–1.4% of each closed primary's voters are enrolled blank today, and major-party-to-major-party movement is unobservable in a single extract. Aggregate enrollment by county and district is published historically by the State Board of Elections and is the natural external validation; **it is incorporated, in Appendix C**, which finds the reconstructed aggregate party shares differing from NYSBOE's published series by at most **1.39 points** across the 2021–2026 snapshots it tests. That is a measured discrepancy over those snapshots, not a bound over the older elections §I also uses, and not a bound on any individual's party at a past election, nor the age-within-party finding §I reports. *(This bullet ended "it is not yet incorporated here" until 2026-08-16 — stale from before Appendix C was written, and contradicted by the paper's own front matter, which already cited that bound.)*
- **Turnout rates are denominated on contemporaneous eligibility.** Every rate in §I, §II's turnout column, and §III counts only registrants enrolled on or before the contest. That is the correct specification and it is not what this paper printed between 2026-08-01 and 2026-08-11 (§I, §III) or until 2026-08-13 (§II) — see the note under §III's table. Composition *shares* (Appendix A, §I, §II's other columns) are a different cut and carry the survivorship caveat below rather than this one.
- **Survivorship, measured rather than assumed.** Voters purged since an election are absent from the file, and purging is invisible in a single extract. Using inactive status as the visible pre-purge state: among 2021 general voters, the inactive rate spans 3.23–3.58% across the four party buckets — a 0.35pp spread, which is what an earlier version was reaching for when it said the bias "hits every group equally," and it is close enough to support cross-party comparison

within a year. Across **age** it does not hold: among 2023 general voters, 2.69% of the under-30 band is now inactive against 1.34% of the 45–64 band. So the age composition shares are biased toward **understating** youth in past electorates. This is a proxy for attrition, not a measurement of it.

- **NOPARTY lean is never imputed.** The blank bloc's partisan sympathies are unobserved; we describe its age, turnout, and matched-donor rate, not its hidden preference, and we do not characterise its political information (its federal *giving*, separately, leans ~2:1 Democratic — see `donor-class-and-the-electorate.md` Finding 3).
- **Vote-history formats.** NYSVOTER mixes ~6 county-specific history formats per election; the normalized parser is validated against known turnout (2024 presidential ≈ 7.4M, the credible figure for the current roll).
- **Competitiveness (§IV uses registration; the safe-seat paper uses observed margins).** Registration lean is a structural proxy, not a vote result; it corroborates the observed map rather than replacing it.

What it means

New York lets us put a party label on every filter between the registered population and the decision: an older general electorate, an older-still off-year electorate with a party-structured age profile in which Republican voters are consistently older than Democratic ones, a closed primary that a young, disengaged quarter of the state cannot enter while unaffiliated, and a district map that is one-sided almost everywhere. The reform implication is the one Washington's data pointed to — **move local elections on-cycle** — but New York adds the evidence that the off-year distortion is party-structured, and that the unaffiliated bloc — the youngest of the state's major enrollment blocs, and the one most heavily represented among recently dated registration records — is least represented in the off-year electorate and, while unaffiliated, ineligible for the party primaries. Combined with the donor-class paper, the picture is a series of narrowing gates — who registers, who votes, who votes in the primary, and who pays — each compositionally different from the one before.

New York has already begun the change, which reframes this paper's contribution. Chapter 741 of the Laws of 2023 moved many town and county offices — supervisor, town board, town clerk, highway superintendent; county executive, comptroller, legislator — from odd-year to even-year Novembers, effective 1 January 2025 and first operative in 2026. It excludes New York City entirely, and it cannot reach sheriff, county clerk, district attorney or the judgeships, whose terms are fixed by Article XIII § 13 of the State Constitution; a constitutional amendment addressing those is advancing. The statute's constitutionality has been litigated and upheld on the state-law claims: the trial court held Chapter 741 unconstitutional under the home-rule article, the Appellate Division, Fourth Department reversed, and the Court of Appeals affirmed unanimously in *County of Onondaga v. State of New York* (16 October 2025), with certiorari denied by the U.S. Supreme Court on 23 March 2026. A separate First Amendment challenge in the Eastern District of New York remains pending: the court dismissed the earlier complaint in June 2026 with leave to replead, the plaintiffs filed a narrowed complaint in July 2026, and in August 2026 they were seeking to enjoin the law's application to that year's elections.

So the recommendation is not a proposal here; it is a policy in its first cycle. That changes what this paper is for. The 2023 and 2025 odd-year electorates measured above are a **statewide pre-transition benchmark** for a live natural-policy experiment — not yet the treatment-specific baseline, since the statewide electorate measured here includes New York City, the constitutionally protected offices, and jurisdictions Chapter 741 does not move. A causal follow-up should restrict the comparison to the jurisdictions and classes of office the statute actually moves, and call that restricted electorate the baseline. Comparing the composition of the same classes of local electorate before and after synchronisation — rather than comparing differently constituted odd- and even-year ballots, which is all the present design can do — is a far stronger, quasi-experimental test of election timing than anything reported here, and the data to run it begins accumulating in November 2026.

Related work

This paper's mechanisms are established; the contribution is the party-resolved, individual-record measurement on 13.5M New York registration and vote records, and the finding that New York's off-year age skew is **party-structured** — Republican off-year electorates are consistently the oldest and the no-party bloc consistently the youngest. It sits in these literatures:

- **Turnout composition by salience (surge-and-decline).** Campbell, "Surge and Decline" (1960); Wolfinger & Rosenstone, *Who Votes?* (1980); Leighley & Nagler, *Who Votes Now?* (2013). Appendix A's presidential→off-year age gradient is this, measured directly. Plutzer, "Becoming a Habitual Voter" (2002) frames the young-adult drop-off in Appendix A.
- **Off-cycle election timing, composition, and representation.** Anzia, *Timing and Turnout* (2014); Hajnal & Trounstine,

"Where Turnout Matters" (2005); Hajnal, Kogan & Markarian, "Who Votes: City Election Timing and Voter Composition" (2022); Einstein , Palmer, Hamilton & Singer, "Age and Homeownership Drive the Local Turnout Gap," *Urban Affairs Review* (2025) — the closest analog to the age result. Motivates the on-cycle remedy.

- **The primary as the real election under one-party dominance.** V.O. Key, *Southern Politics in State and Nation* (1949); Hirano & Snyder, *Primary Elections in the United States* (2019). Key supplies the theoretical expectation; §IV measures the registration structure that would motivate testing it. New York does not claim itself as an observed modern instance — that needs the seat-by-seat primary/general analysis §III and §IV defer to future work.
- **Primary-electorate representativeness (the tension).** Sides, Tausanovitch, Vavreck & Warshaw, "On the Representativeness of Primary Electorates" (2020) — distinguished here: our claim is composition and closure (Section III), not ideological extremism.
- **Independents / the unaffiliated.** Klar & Krupnikov, *Independent Politics* (2016); Fiorina, "The (Re)Nationalization of Congressional Elections" and the broader dealignment literature — the frame for the young, disengaged unaffiliated quarter that sits outside the closed primary (Section II) and for what Section V can and cannot say about no-party enrollment among recently *dated* registration records. *(Until 2026-08-26 this read "the new-registrant abandonment of party labels (Section V)" and described a "locked-out unaffiliated quarter". Both are withdrawn upstream and were still live here. §V establishes that* `registration_date` *is the date of the most recent registration TRANSACTION, not necessarily first registration — at least 9.96% of the 2020 row and 13.91% of the 2024 row are re-registrations, and those two figures are not comparable to each other — so "new registrant" is not a population this file identifies. And §II's own institutional language is that the unaffiliated are outside the primary, not locked out of the electorate.)*
- **Voter-file / individual-level method.** Ansolabehere & Hersh, "Validation: What Big Data Reveal About Survey Misreporting and the Real Electorate" (2012); Hersh, *Hacking the Electorate* (2015). On the current-roll survivorship caveat (Boundary of inference): Huber, Meredith, Morse & Steele, "The Racial Burden of Voter List Maintenance Errors: Evidence from Wisconsin's Supplemental Movers Poll Books," *Science Advances* 7(8):eabe4498 (2021), on list-maintenance error; and Feder & Miller, "Voter Purges After *Shelby*," *American Politics Research* 48(6):687–692 (2020), on differential purge rates — the mechanism that would make this paper's attrition non-neutral. An earlier version cited a single work combining the two, attributing Huber et al.'s title and journal to Feder and Miller; they share no authors.

Methods & reproducibility

```
python scripts/load_ny_voters.py                          # NYSVOTER FOIL -> ny_vrdb.duckdb
python scripts/diag_ny_turnout_party.py --rebuild         # turnout by age x party (App. A, I)
STATE=NY python scripts/diag_ny_primary_participation.py # closed-primary participation (III)
STATE=NY python scripts/diag_ny_electorate_extras.py      # blank bloc / decomposition / registration m
python scripts/pin_ny_roll.py                             # freeze the roll-denominated denominator
python scripts/diag_ny_enrollment_validation.py           # vs NYSBOE published enrollment (App. C)
python scripts/verify_who_decides_ny.py                   # assert every figure above against the file
```

All inputs are public records (NY NYSVOTER under its lawful-use FOIL terms). See `data-sources-and-reproducibility.md` for the source ledger and method notes, and `ny-electorate-extras.md` and `ny-turnout-by-party-age.md` for the extended underlying tables (the latter regenerated 2026-08-29 against the current pipeline; this paper owns the citable claims, and where a basis differs the companion's own notes say which is published here).

Appendix A — Validation: the off-year electorate is older

This is a replication, and it is placed here for that reason. That the electorate ages as salience falls has been established since Campbell (1960) and measured for local elections by Anzia (2014); New York adds scale and individual records, not a new claim. The paper's contribution begins at Section I, which asks which party's electorate is older and whether that ordering persists across election types. This appendix exists so that premise is measured rather than assumed, and so a reader can check it against the sources in Related work.

Share of the general-election electorate by age band:

Election	Type	18–29	30–44	45–64	65+	median

Election	Type	18–29	30–44	45–64	65+	median
Nov 2024	Presidential	**14.1%**	23.1%	34.6%	28.2%	53
Nov 2022	Midterm	9.8%	21.1%	38.5%	30.6%	56
Nov 2025	Off-year	11.5%	21.0%	33.1%	34.4%	56
Nov 2023	Off-year	**6.0%**	15.9%	36.5%	**41.6%**	61

Both odd-year electorates are older than the 2024 presidential one, though the sequence is not monotonic in salience (the midterm and the 2025 odd-year sit between the extremes, and not in that order — see below). From the presidential electorate to the 2023 odd-year, the under-30 share collapses (14% → 6% by 2023) and the 65+ share swells (28% → 42%); median age rises from 53 to 61. **Behavior, not rolls.** A Das-Gupta decomposition of the 65+ share rise from 2024 to 2025 attributes it several times more to differential **turnout** than to the registration age structure (rate effect **+2.5 to +8.7 pts** vs composition +0.6 to +1.5, depending on party — a 3.6× ratio for Democrats up to 12.5× for the unaffiliated). What the decomposition establishes is that the 2024-to-2025 increase is a **participation** pattern rather than a registration artifact — for that one change, not for the other years or the full off-cycle pattern. It does not establish the cause of the participation gap.

And "odd year" is not one treatment — this table says so itself. The two odd-year electorates differ enormously: 2023 turned out 2,336,272 voters at 41.6% aged 65+, while 2025 turned out 4,039,285 — **1.73×** as many — at 34.4%. Different offices, candidates, salience and geography sit behind those two rows, so an odd-year November is a bundle of conditions, not a manipulated variable. No election was moved in this design. The off-cycle literature cited above supports the causal timing claim; what these data can say is that they are consistent with it. Chapter 741 (see "What it means") is about to supply the design that would settle it.

Like Section I, this table is **electorate**-denominated: it describes the set of people who actually cast a ballot in a past election, which cannot change when new registrants are added to the roll. That is why all of its cells reproduced unchanged through the 2026-08-01 recomputation that moved Sections II and III — see the note under Section III.

Appendix C — External validation against NYSBOE published enrollment

The two limitations in the front matter — current-party labelling and current-roll survivorship — both bear on one quantity: the party composition of the people who were on the roll at some past date. They need not push it the same way — party switching and re-registration can offset — so this is not a single signed bound. New York publishes an external check on that quantity in aggregate, and this appendix uses it: across the 2021–2026 snapshots it compares, the reconstructed aggregate party shares differ from NYSBOE's by only a small margin (the largest is given below). That is a measured discrepancy over those snapshots, not a bound over the full historical period §I uses, and not a bound on any individual's party at a past election or on the age-within-party estimates §I reports. NYSBOE's *NYSVoter Enrollment by County, Party Affiliation and Status* gives statewide enrollment by party, split active/inactive, twice a year back to 2006.

For each snapshot date *D* we compare NYSBOE's published active shares against the shares among registrants in our extract who registered on or before *D* and are **active today**. The gap is the net of party switching, purges, active-to-inactive transitions, NYSBOE's own revisions, and one selection effect this design introduces: because the extract dates each registrant by their *most recent* registration transaction, a voter who was on the roll at *D* but re-registered after it (§V shows this is common) carries a date after *D* and drops out of the comparison, so the reconstructed sample is not exactly the roll as it stood at *D*.

Snapshot	Precedes	DEM	REP	NOPARTY	OTHER	file/published actives
2026-02-20	**control**	-0.17	+0.10	-0.26	+0.33	**98.08%**
2025-11-01	the 2025 general	-0.17	+0.10	-0.24	+0.31	96.63%
2024-02-27	both 2024 primaries	-0.34	+0.57	-0.16	-0.07	91.89%
2022-02-21	the 2022 primary	-1.02	+1.15	+0.20	-0.33	84.89%
2021-02-21	the 2021 primary	-1.06	**+1.39**	+0.11	-0.44	**78.64%**

Gaps in percentage points of the active roll; positive means the surviving 2026 sample over-represents that bucket. The February observations are the nearest

available NYSBOE post-deadline snapshots; New York's statutory party-change cutoff for the June primary falls on February 14, and these snapshots sit just after it. Buckets map as NOPARTY = NYSBOE's BLANK and OTHER = CON + WOR + OTH. Derived by `scripts/diag_ny_enrollment_validation.py`.

Read the control row first. It sits about four months before the extract, so drift has had almost no time to accumulate, and its gaps are -0.26 to +0.33. Had the method been mis-specified — wrong active filter, wrong bucketing, wrong denominator — that row would be off too and everything below it would be measuring our own error rather than New York's.

Three things follow.

1. **The largest discrepancy across the tested snapshots is small.** Across the 2021–2026 validation snapshots, the largest observed aggregate gap is **1.39 points**, on the Republican share five and a half years back. It measures how far the reconstructed aggregate party shares sit from NYSBOE's published shares over those snapshots; it is not a bound over the older elections §I also uses (2016–2020, which the validation series here does not cover), not a ceiling on any individual's party at a past election, nor on the age-within-party finding, and it should not be used as a correction factor. Nothing here decomposes it into switching versus purging.
2. **The aggregate direction runs against a naive reading of the party shares.** The surviving sample under-represents Democrats and over-represents Republicans at every historical date, so a 2026-labelled reconstruction makes the reconstructed historical rolls look slightly *more* Republican in aggregate than they were. *(This read "the §I finding is that the Republican electorate ages hardest" until 2026-08-26. §I withdrew that dynamic framing on 2026-08-16 and gives five independent reasons for doing so — the R−D gap does NOT widen off-cycle, and 2023 reverses the ordering the framing was built on. An appendix describing the direction of a bias against a finding the paper no longer makes is the propagation failure this series keeps paying for; the correction is to name the finding §I actually states.)* This is a statement about the aggregate party shares and does not carry to the age-within-party finding — the within-party estimand this appendix does not validate — and it is why §I leads with median age and 65+ share *within* each party rather than with the parties' relative sizes.
3. **Coverage loss is large while the aggregate composition difference is small.** The reconstruction captures **78.64%** as many qualifying records as NYSBOE counted active in February 2021 — and yet the aggregate party composition differs by at most 1.39 points. That shortfall cannot be read as attrition alone: a registrant who was active at the date but re-registered afterward carries a later date and drops from the reconstructed pre-date sample, so some of the missing fifth are not gone at all. What survives is the quantitative version of the claim an earlier draft made without evidence when it called composition shares "robust" — they are more robust than the turnout rates, and now there is a number for how much.

What this does **not** address is the reviewer's sharpest point: aggregate enrollment cannot recover any individual's party at a past election, so it validates composition without recovering party-at-election. That remains open, and no source we know of closes it for New York without contemporaneous individual snapshots.

Appendix B — Section numbering, before and after 2026-08-06

The paper was reordered on 2026-08-06 to open on its party-resolved result rather than on its replication. **Only the order and the numbering changed; no figure, table cell, or claim was altered by the reordering.** This map is recorded because earlier documents in this series — including the append-only `electoral-health-audit-log.md` — cite these sections by number, and a silent renumbering would re-point those citations at different content.

Before	After	Content
§I	**Appendix A**	The off-year electorate is older (replication / validation)
§II	**§I**	The graying is not partisan-neutral
§III	**§II**	The unaffiliated quarter
§IV	**§III**	The nominating electorate
§V	**§IV**	The registration map (titled "Safe-seat New York" until 2026-08-11)
§VI	**§V**	Recently dated registration records are more often no-party

So a pre-2026-08-06 reference to "NY §III/§IV" — the roll-denominated blocks recomputed on 2026-08-01 — is a reference to what are now **§II and §III**.
